

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

right perception and logical framing of ideas are out of the question. In the fields of volition and emotion the obscurity is as great. With its depth the expression of it changes from a simple dazed condition to one resembling coma. Upon this simple background may appear illusions, hallucinations, and delusions to such a degree as to color the whole; and since the condition frequently enters only as a stage in a complicated psychosis, it is apt to be still further overlaid by the residua of delusions from earlier stages; whence its confusion with primary dementia and paranoia, the two extremes between which it varies. A typical case begins and ends with periods of disturbance of consciousness passing through a delirious stage between the two, and having a favorable prognosis in proportion as the obscurity of consciousness is deep. For the author, as for Wundt, consciousness has a functional side, and it is by no means simple. It involves the regulative ideas of the *ego*, cause, time and space, etc., and by its complexity makes possible a "change of consciousness as a whole, which to a certain extent is independent of the quantitative and qualitative change of the elements of consciousness, as also of the psychic function, *i. e.* of the framing and working over of ideas."

Klinische Beiträge zur Kenntniss der generellen Gedächtnisschwäche.
Dr. C. S. FREUND. Archiv f. Psychiatrie, Bd. XX, H. 2.

The author has observed two cases of pathological weakness of memory. Both were women, one 52, the other 65; both had suffered severe nervous troubles from alcoholic excess, leading up to psychical disturbances, after which the chief remaining symptom was the weakness of memory, complicated in one case by senile dementia. In both the sensorium was clear of hallucinations and sense illusions, apperception little affected, and untroubled by delusions; bodily disease was absent, except in one, whose trouble was tabetic. The memory of things in early life (before 30 in the first, before 20 in the other) was much better than for recent events. The first could not remember her own bed, nor the day of the week, nor, after a few hours, whether or not she had dined. She forgot repeatedly the name and use of a stethoscope that was shown to her and explained; she could only repeat phrases of some length when spoken slowly and distinctly and perhaps repeated. Similarly with tunes, and the first tune of several seemed best remembered. She could multiply numbers, but forgot the examples; she could, however, remember a number over a period of conversation about other things. She showed also illusions of memory. Her power to write was not affected. In the second case, however, this was an interesting feature. In spontaneous writing she repeated words in whole or in part, together with parts of words to follow, before getting the latter written correctly. She had difficulty in recalling the capital letters, though what was at the instant forgotten often returned later. Writing from a copy became almost free of errors when she spelled the words aloud as she wrote. Writing from dictation was worst of all. In the dictated alphabet errors seemed to occur in proportion to speed. The patient could recognize errors, and the disturbances varied with her power of memory. That sufficed for her to spell polysyllabic words orally, but not to write them, and in spelling she was apt to add letters after completing the word. In other particulars she resembled the first case.
